

Security risk assessment report

Part 1: Select up to three hardening tools and methods to implement

1. Multifactor Authentication (MFA) — addresses the lack of MFA and password sharing
2. Password Policies — addresses the default admin password and shared passwords
3. Firewall Maintenance / Port Filtering — addresses the firewall having no filtering rules

Part 2: Explain your recommendations

1. Multifactor Authentication (MFA)

MFA is effective because even if someone guesses or steals a password, they still can't get in without the second verification step. In this case, the data breach happened partly because MFA wasn't in place. It only needs to be set up once and then maintained going forward.

2. Password Policies

The admin database was using a default password, and employees were sharing passwords both are serious risks. Enforcing strong password policies (like hashing, salting, and no password sharing) makes it much harder for attackers to gain access. This should be implemented immediately and reviewed regularly.
